## 08: File I/O

Version: August 8, 2019

# Contents

00: Introduction: Overview, Code Building, IDE
01: Basic: Elements of C Program, Identifiers, Data Types
02: Branching: Conditional expressions, logical operators
03: Branching: selection, if-else, while, switch
04: Loops: repetition, for, do-while
05: Increment/decrement, nested loops, loop tracing
06: Functions: declaration, definitions, calls
07: Pointers and addresses: pass by reference, pointer arithmetic
08: File I/O
09: Arrays: declarations, initialization, search, sort
10: Strings
11: Recursion
12: Structures
13: Applications
14: Revisions

# FILE \*

- ◆ In C, we use a FILE \* data type to access files.
- ◆ FILE \* is defined in /usr/include/stdio.h
- ◆ An example:

```
#include <stdio.h>
```

```
int main()
```

```
{
```

```
    FILE *fp;
```

```
    fp = fopen("tmp.txt", "w");
```

```
    fprintf(fp, "This is a test\n");
```

```
    fclose(fp);
```

```
    return 0;
```

```
}
```

# Opening a File (1)

- ◆ You must include `<stdio.h>`
- ◆ Prototype Form:  
`FILE * fopen (const char * filename, const char * mode)`
- ◆ `FILE` is a structure type declared in `stdio.h`.
  - You don't need to worry about the details of the structure.
    - ❖ In fact it may vary from system to system.
  - `fopen` returns a pointer to the `FILE` structure type.
  - You must declare a pointer of type `FILE` to receive that value when it is returned.
  - Use the returned pointer in all subsequent references to that file.
  - If `fopen` fails, `NULL` is returned.
- ◆ The argument `filename` is the name of the file to be opened.

## Opening a File (2)

### Values of `mode`

- ◆ Enclose in double quotes or pass as a string variable
- ◆ Modes:
  - `r`: open the file for reading (NULL if it doesn't exist)
  - `w`: create for writing. destroy old if file exists
  - `a`: open for writing. create if not there. start at the end-of-file
  - `r+`: open for update (r/w). create if not there. start at the beginning.
  - `w+`: create for r/w. destroy old if there
  - `a+`: open for r/w. create if not there. start at the end-of-file
- ◆ In the text book, there are other binary modes with the letter `b`. They have no effect in today's C compilers.

## stdin, stdout, and stderr

---

- ◆ Every C program has three files opened for them at start-up: `stdin`, `stdout`, and `stderr`
- ◆ `stdin` is opened for reading, while `stdout` and `stderr` are opened for writing
- ◆ They can be used wherever a `FILE *` can be used.
- ◆ Examples:
  - `fprintf(stdout, "Hello there!\n");`
    - ❖ This is the same as `printf("Hello there!\n");`
  - `fscanf(stdin, "%d", &int_var);`
    - ❖ This is the same as `scanf("%d", &int_var);`
  - `fprintf(stderr, "An error has occurred!\n");`
    - ❖ This is useful to report errors to standard error - it flushes output as well, so this is really good for debugging!

# The exit () Function

- ◆ This is used to leave the program at anytime from anywhere before the “normal” exit location.
- ◆ Syntax:

`exit (status);`

- ◆ Example:

```
#include <stdlib.h>
```

```
.....
```

```
if( (fp=fopen("a.txt","r")) == NULL){  
    fprintf(stderr, "Cannot open file a.txt!\n");  
    exit(1);  
}
```

# Four Ways to Read and Write Files

---

- ◆ Formatted file I/O
- ◆ Get and put a character
- ◆ Get and put a line
- ◆ Block read and write

## Formatted File I/O

- ◆ Formatted File input is done through **fscanf**:
  - **int fscanf (FILE \* fp, const char \* fmt, ...) ;**
- ◆ Formatted File output is done through **fprintf**:
  - **int fprintf(FILE \*fp, const char \*fmt, ...);**

```
{  
    FILE *fp1, *fp2;  
    int n;  
    fp1 = fopen("file1", "r");  
    fp2 = fopen("file2", "w");  
    fscanf(fp1, "%d", &n);  
    fprintf(fp2, "%d", n);  
    fclose(fp1);  
    fclose(fp2);  
}
```

## Get and Put a Character

---

```
#include <stdio.h>
```

```
int fgetc(FILE * fp);
```

```
int fputc(int c, FILE * fp);
```

- ◆ These two functions read or write a single byte from or to a file.
- ◆ **fgetc** returns the character that was read, converted to an integer.
- ◆ **fputc** returns the same value of parameter c if it succeeds, otherwise, return EOF.

## Get and Put a Line

---

```
#include <stdio.h>
```

```
char *fgets(char *s, int n, FILE * fp);
```

```
int fputs(char *s, FILE * fp);
```

- ◆ These two functions read or write a string from or to a file.
- ◆ **fgets** reads an entire line into **s**, up to **n-1** characters in length (pass the size of the character array **s** in as **n** to be safe!)
- ◆ **fgets** returns the pointer **s** on success, or NULL if an error or end-of-file is reached.
- ◆ **fputs** returns the number of characters written if successful; otherwise, return EOF.

# fwrite and fread (1)

- ◆ **fread** and **fwrite** are binary file reading and writing functions
  - Prototypes are found in `stdio.h`
- ◆ Generic Form:
  - `int fwrite (void *buf, int size, int count, FILE *fp) ;`
  - `int fread (void *buf, int size, int count, FILE *fp) ;`
  - ❖ **buf**: is a pointer to the region in memory to be written/read
    - It can be a pointer to anything (more on this later)
  - ❖ **size**: the **size** in bytes of each individual data item
  - ❖ **count**: the number of data items to be written/read
- ◆ For example a 100 element array of integers
  - `fwrite( buf, sizeof(int), 100, fp);`
- ◆ The **fwrite** (**fread**) returns the number of items actually written (read).

## fwrite and fread (2)

- ◆ Testing for errors:

```
if ((fwrite(buf,size,count,fp)) != count)
    fprintf(stderr, "Error writing to file.");
```

- ◆ Writing a single double variable x to a file:

```
fwrite (&x, sizeof(double), 1, fp) ;
```

- This writes the double x to the file in raw binary format
  - ❖ i.e., it simply writes the internal machine format of x

- ◆ Writing an array text[50] of 50 characters can be done by

- `fwrite (text, sizeof(char), 50, fp) ;`
  - ❖ or
- `fwrite (text, sizeof(text), 1, fp); /* text must be a local array name */`

- ◆ `fread` and `fwrite` are more efficient than `fscanf` and `fprintf`

# Closing and Flushing Files

---

- ◆ Syntax:

  - `int fclose (FILE * fp) ;`

  - ❖ closes `fp` -- returns 0 if it works -1 if it fails

- ◆ You can clear a buffer without closing it

  - `int fflush (FILE * fp) ;`

  - ❖ Essentially this is a force to disk.

  - ❖ Very useful when debugging.

- ◆ Without `fclose` or `fflush`, your updates to a file may not be written to the file on disk.  
(Operating systems like Unix usually use “write caching” disk access.)

## Sequential and Random Access

- ◆ In the FILE structure, there is a long type to indicate the position of your next reading or writing.
- ◆ When you read/write, the position move forward.
- ◆ You can “rewind” and start reading from the beginning of the file again:

`void rewind (FILE * fp) ;`

- ◆ To determine where the position indicator is use:

`long ftell (FILE * fp) ;`

- ❖ Returns a long giving the current position in bytes.
- ❖ The first byte of the file is byte 0.
- ❖ If an error occurs, `ftell ()` returns -1.

# Random Access

- ◆ One additional operation gives slightly better control:

`int fseek (FILE * fp, long offset, int origin) ;`

- `offset` is the number of bytes to move the position indicator
- `origin` says where to move from

- ◆ Three options/constants are defined for `origin`

- `SEEK_SET`

- ❖ move the indicator offset bytes from the beginning

- `SEEK_CUR`

- ❖ move the indicator offset bytes from its current position

- `SEEK_END`

- ❖ move the indicator offset bytes from the end

# Detecting End of File

## ◆ Text mode files:

```
while ( (c = fgetc (fp) ) != EOF )
```

- Reads characters until it encounters the EOF
- The problem is that the byte of data read may actually be indistinguishable from EOF.

## ◆ Binary mode files:

```
int feof (FILE * fp) ;
```

- Note: the `feof` function realizes the end of file only **after** a reading failed (`fread`, `fscanf`, `fgetc` ... )

```
fseek(fp,0,SEEK_END);
```

```
printf("%d\n", feof(fp));           /* zero value      */
```

```
fgetc(fp);                          /* fgetc returns -1 */
```

```
printf("%d\n", feof(fp));           /* nonzero value   */
```

# An Example

---

```
#define BUFSIZE 100
int main () {
    char buf[BUFSIZE];
    if ( (fp=fopen("file1", "r"))==NULL) {
        fprintf (stderr,"Error opening file.");
        exit (1);
    }
    while (!feof(fp)) {
        fgets (buf,BUFSIZE,fp);
        printf ("%s",buf);
    }
    fclose (fp);
    return 0;
}
```

# File Management Functions

---

## ◆ Erasing a file:

`int remove (const char * filename);`

- ❖ This is a character string naming the file.
- ❖ Returns 0 if deleted; otherwise -1.

## ◆ Renaming a file:

`int rename (const char * oldname, const char * newname);`

- ❖ Returns 0 if successful or -1 if an error occurs.
- ❖ error: file `oldname` does not exist
- ❖ error: file `newname` already exists
- ❖ error: try to rename to another disk

# Using Temporary Files

---

- ◆ Files that only exist during the execution of the program.
- ◆ Generic Form:  
`char *tmpnam (char *s) ;`
  - Included in stdio.h.
  - Creates a valid filename that does not conflict with any other existing files.
- ◆ Note this does not create the file
  - Just the NAME!
  - You then go and open it and presumably write to it.
  - The file created will continue to exist after the program executes unless you delete it.

# An Example

---

```
#include <stdio.h>
int main () {
    char buffer[25];
    tmpnam(buffer);
    printf ("Temporary name 1: %s", buffer);
    return 0;
}
```

## ◆ Output

Temporary name 1: /var/tmp/aaaceaywB
